Executive Summary

>Omited Text<, requested an Expedited System Impact Study under the Southwest Power Pool (SPP) Open Access Transmission Tariff (OATT) to determine the impact of developing a 110 MW wind generating plant in Butler County, Kansas. The proposed >Omited Text< plant includes a 138 kV interconnection to the Westar Energy, Inc. (WR) Altoona – Butler 138 kV transmission line. The proposed facility is expected to be in commercial operation by February 2003.

The principal objectives of this study were:

?? Evaluate the potential for system problems resulting from the interconnection.

?? Evaluate the potential modifications required to effect the interconnection.

The estimated interconnection facility costs to connect the proposed >Omited Text< plant to the WR transmission system are estimated at $0.630 million. There are no estimated overutilized equipment replacement costs on the WR transmission system. The required interconnection costs for the proposed >Omited Text< plant are the interconnection facility costs. The estimated transmission service mitigation costs for system improvements on the WR transmission system necessary to transmit the full output of the proposed >Omited Text< plant are $8.358 million.

Power flow studies were conducted to evaluate possible transmission impacts associated with scheduling power out of the proposed >Omited Text< plant. Power flow studies used 2003 spring, summer, summer-shoulder, fall and winter peak, 2005 summer and winter peak, and 2008 summer and winter peak models. Changes were incorporated to evaluate the proposed >Omited Text< plant. Short circuit and transient stability studies were conducted to evaluate interconnection impacts of the proposed >Omited Text< plant. Short circuit studies used 2002 summer peak and 2005 summer peak models. Transient stability studies used a 2005 summer peak model.

Certain facilities are required to connect the proposed >Omited Text< plant to the existing Altoona – Butler 138 kV transmission line. The estimated interconnection facility costs are shown in Table 1.

Results of power flow studies through 2008/09 winter peak conditions are that the addition of the proposed >Omited Text< plant requires transmission facility upgrades to effect a transfer of the full output of the proposed >Omited Text< plant under all conditions. The estimated transmission service mitigation costs are shown in Table 2. Results of short circuit studies are that the addition of the proposed >Omited Text< plant requires no equipment upgrades based on fault current considerations. Results of transient stability studies are that the addition of the proposed >Omited Text< plant does not require additional equipment or equipment upgrades based on transient stability considerations.
Introduction

>Omited Text<, requested an Expedited System Impact Study under the SPP OATT to determine the feasibility of developing a 110 MW generating plant in Butler County, Kansas. The proposed >Omited Text< plant includes a 138 kV interconnection to the Westar Energy, Inc. (WR) Altoona – Butler 138 kV transmission line. The proposed facility is expected to be in commercial operation by February 2003.

Previously completed was a Feasibility Study. This System Impact Study is a continuation of generation interconnection evaluation under the regional Open Access Transmission Tariff administered by the Southwest Power Pool (SPP).

System conditions were also studied using power flow for both normal (no lines out) and single-contingency outage conditions to evaluate possible transmission service limitations. The seasons evaluated were 2003 spring, summer, summer-shoulder, fall and winter peak, 2005 summer and winter peak, and 2008 summer and winter peak. Power flow analyses were evaluated using SPP Criteria. Specifically, facility loading greater than 100 percent of normal rating during base case conditions or facility loading greater than 100 percent of emergency rating during single-contingency outage conditions required mitigation. Transmission facilities subject to monitoring for adverse impact were those operated at 69 kV or greater in the general area of the proposed >Omited Text< plant. The power flow studies assume that the output of the proposed >Omited Text< plant is delivered into the Westar Energy control area and not transmitted out of the control area.

For purposes of evaluating the interconnection of the proposed >Omited Text< plant, short circuit and transient stability studies were performed. These studies identified any equipment that may require upgrades due solely to the generation interconnection. System conditions studied using short circuit model were 2002 summer peak conditions. System conditions studied using a transient stability model were 2005 summer peak conditions using data provided by SPP.

Power Flow Studies

SPP developed base cases for the seasons studied were used. Data representing the proposed >Omited Text< plant was added to each base case. The full output of the proposed >Omited Text< plant was assumed to be delivered to the WR control area. Automatic single-contingency analysis of the base case and of the case with the proposed plant added was performed for each season to determine if facility overloads were created due to the addition of the proposed >Omited Text< plant. Incremental improvements were made to mitigate any overloads. In this way, the minimum improvements necessary were determined. Estimated transmission service mitigation costs were identified and are shown in Table 2. The results of the power flow studies are summarized in Appendix 1.
Short Circuit Studies

An SPP developed base case for the 2002 summer peak season was used. Data representing the proposed >Omitted Text< plant was added to the base case. Automatic short circuit calculations were performed to determine if equipment were overdutied due to the addition of the proposed >Omitted Text< plant. System improvements determined by the power flow studies were then added to the appropriate short circuit models and the fault calculations repeated. The fault calculations were repeated for the two proposed >Omitted Text< plant configurations. Three-phase and single-phase-to-ground faults were applied at buses in the vicinity of the proposed plant to evaluate the impact on equipment. Overdutied equipment was reported. Estimated overdutied equipment replacement costs were identified.

Transient Stability Studies

An SPP developed base case for the 2005 summer peak season was used. Data representing the proposed >Omitted Text< plant was added to the base case, fault conditions were applied, and the transient performance of the area was monitored. The studies were repeated without and with the proposed >Omitted Text< plant in service. The transient stability studies did not consider whether or not certain prospective merchant plants with requests for interconnection ahead of the proposed >Omitted Text< plant were in service, because of locational distances.

Required Interconnection Facilities

In order to connect the proposed >Omitted Text< plant to WR’s electric transmission system, system improvements are required. A double circuit tap from the existing Altoona – Butler 138 kV line connects to the >Omitted Text< plant substation. Existing protective relaying at Butler will be relocated to the >Omitted Text< plant substation and new relaying installed at Butler. Interconnection metering is installed at the >Omitted Text< plant substation. Lightning protection is added on the Butler – >Omitted Text< plant 138 kV transmission line. No additional facilities are required solely for interconnection to the Altoona – Butler 138 kV transmission line. Estimated interconnection facility costs total $0.630 million (excluding potential tax consequences) and are shown in Table 1. The costs in Table 1 are required costs for interconnection of the proposed >Omitted Text< plant. Also shown in Table are potential tax consequences, which may increase the cost to $0.819 million. It is assumed that >Omitted Text< will construct and own the proposed plant substation.

Discussion of Results – Power Flow Studies

2003 Spring Peak

During 2003 spring peak conditions with no lines out of service, the full output of the proposed >Omitted Text< plant does not cause overloads or low voltages. During 2003 spring peak
conditions, the full output of the proposed >Omitted Text< plant does not cause new overloads during single-contingency outage conditions.

2003 Summer Peak
During 2003 summer peak conditions with no lines out of service, the full output of the proposed >Omitted Text< plant does not cause overloads or low voltages. During 2003 summer peak conditions, the full output of the proposed >Omitted Text< plant causes new overloads during single-contingency outage conditions. Facilities that exceed emergency rating during a single-contingency outage and the emergency rating are:

5.73-mile Weaver – Rose Hill Tap 69 kV line, 43 MVA

2003 Summer Shoulder Peak
During 2003 summer shoulder peak conditions with no lines out of service, the full output of the proposed >Omitted Text< plant does not cause overloads or low voltages. During 2003 summer shoulder peak conditions, the full output of the proposed >Omitted Text< plant does not cause new overloads during single-contingency outage conditions.

2003 Fall Peak
During 2003 fall peak conditions with no lines out of service, the full output of the proposed >Omitted Text< plant does not cause overloads or low voltages. During 2003 fall peak conditions, the full output of the proposed >Omitted Text< plant does not cause new overloads during single-contingency outage conditions.

2003/04 Winter Peak
During 2003/04 winter peak conditions with no lines out of service, the full output of the proposed >Omitted Text< plant does not cause overloads or low voltages. During 2003/04 winter peak conditions, the full output of the proposed >Omitted Text< plant causes new overloads during single-contingency outage conditions. Facilities that exceed emergency rating during a single-contingency outage and the emergency rating are:

15.70-mile Butler – >Omitted Text< 138 kV, 110 MVA

2005 Summer Peak
During 2005 summer peak conditions with no lines out of service, the full output of the proposed >Omitted Text< plant does not cause overloads or low voltages. During 2005 summer peak conditions, the full output of the proposed >Omitted Text< plant causes new overloads during single-contingency outage conditions. Facilities that exceed emergency rating during a single-contingency outage and the emergency rating are:

5.73-mile Weaver – Rose Hill Tap 69 kV line, 43 MVA
2005/06 Winter Peak
During 2005/06 winter peak conditions with no lines out of service, the full output of the proposed Omitted Text plant does not cause overloads or low voltages. During 2005/06 winter peak conditions, the full output of the proposed Omitted Text plant causes new overloads during single-contingency outage conditions. Facilities that exceed emergency rating during a single-contingency outage and the emergency rating are:

15.70-mile Butler – Omitted Text 138 kV, 110 MVA

2008 Summer Peak
During 2008 summer peak conditions with no lines out of service, the full output of the proposed Omitted Text plant does not cause overloads or low voltages. During 2008 summer peak conditions, the full output of the proposed Omitted Text plant does not cause new overloads during single-contingency outage conditions.

2008/09 Winter Peak
During 2008/09 winter peak conditions with no lines out of service, the full output of the proposed Omitted Text plant does not cause overloads or low voltages. During 2008/09 winter peak conditions, the full output of the proposed Omitted Text plant causes new overloads during single-contingency outage conditions. Facilities that exceed emergency rating during a single-contingency outage and the emergency rating are:

15.70-mile Butler – Omitted Text 138 kV, 110 MVA

Discussion of Results – Short Circuit Studies

2002 Summer Peak
During 2002 summer peak conditions, the addition of the proposed Omitted Text plant does not cause existing equipment to exceed their interrupting duties.

Discussion of Results – Transient Stability Studies

2005 Summer Peak
During 2005 summer peak conditions, the addition of the proposed Omitted Text plant does not cause stability problems in the area.

Transmission Service Mitigation

Although no requests for transmission service are made concurrent with this request for generation interconnection, based on the results of power flow studies certain transmission system improvements are required to transmit the full output of the proposed plant into the WR control area under all conditions.
2003 Summer Peak – Rebuild the 5.73-mile Weaver – Rose Hill Tap 69 kV transmission line. The existing transmission line is 1920s vintage and is sag limited by 2/0 AWG copper conductor to 43 MVA. The rebuilding project would be a complete tear-down and rebuild using all new structures and conductor.

2003/04 Winter Peak – Rebuild the 15.70-mile Butler – >Omitted Text< 138 kV transmission line. The existing transmission line is 1924 vintage and is sag limited by 266.8 kcmil ACSR conductor to 110 MVA. The rebuilding project would be a complete tear-down and rebuild using all new structures and conductor.
